

Carbene-Catalyzed α -Carbon Amination of Chloroaldehydes for Enantioselective Access to Dihydroquinoxaline DerivativesRuoyan Huang,^{†,||} Xingkuan Chen,^{§,||} Chengli Mou,^{‡,||} Guoyong Luo,[‡] Yongjia Li,[§] Xiangyang Li,[†] Wei Xue,^{*,†} Zhichao Jin,^{†,||} and Yonggui Robin Chi^{*,†,§,||}[†]Laboratory Breeding Base of Green Pesticide and Agricultural Bioengineering, Key Laboratory of Green Pesticide and Agricultural Bioengineering, Ministry of Education, Guizhou University, Huaxi District, Guiyang 550025, China[‡]Guizhou University of Traditional Chinese Medicine, Huaxi District, Guiyang 550025, China[§]Division of Chemistry & Biological Chemistry, School of Physical & Mathematical Sciences, Nanyang Technological University, Singapore 637371, Singapore

Supporting Information

ABSTRACT: An NHC-catalyzed α -carbon amination of chloroaldehydes was developed. Cyclohexadiene-1,2-diimines are used as amination reagents and four-atom synthons. Our reaction affords optically enriched dihydroquinoxalines that are core structures in natural products and synthetic bioactive molecules.

Dihydroquinoxalines and their derivatives are frequently found as core structures in natural and non-natural molecules with proven biological activities.¹ They have been intensively studied as potential drugs for the treatment of multiple diseases such as HIV infections,^{1a} atherosclerosis,^{1b} and allergies^{1c} (Figure 1a). Considerable attention has therefore been focused toward the synthesis of dihydroquinoxalines especially in enantiomerically enriched forms.^{2–5} Main approaches include chiral amine catalyzed hetero-Diels–Alder reactions of *o*-benzoquinone diimides with various carbonyl compounds,³ copper-catalyzed cross-couplings of α -amino acids with substituted anilines,⁴ and asymmetric hydrogenation of substituted quinoxaline derivatives enabled by either transition metals or chiral Brønsted acids.⁵ Despite these elegant advancements, metal-free and operationally simple methods are still needed for the asymmetric synthesis of these molecules.

N-Heterocyclic carbene (NHC) organic catalysis⁶ can in principle offer effective solutions in this direction. Studies have shown that asymmetric carbon–nitrogen bonds can be constructed via NHC catalysis by using diazenes as the electronic amination reagents (Figure 1b), as reported by Scheidt,⁷ Ye,⁸ Smith,⁹ and Zhong.¹⁰ These methods provide pyrazolidinones,⁷ 1,3,4-oxadiazin-6-ones,^{8a,10} α -hydrazino esters,⁹ and dihydropyridazinones^{8b} as the products. We recently reported nucleophilic β -carbon-atom amination of enals, in which a protected hydrazine behaved as a nucleophilic nitrogen reaction center.¹¹ In these studies from us and others,¹² the amination reagents behave as two-atom synthons and end up with a “C–N–N–C” fragment in the final products (Figure 1b). Here we disclose that cyclohexadiene-1,2-diimine can behave as an effective amination reagent that functionalizes the α -carbon of chloroaldehydes under NHC

catalysis (Figure 1c). The cyclohexadiene-1,2-diimine reacts as a four-atom synthon and leads to a cyclic “C–N–C–C–N–C” fragment fused with a benzene that is exactly the core component in dihydroquinoxaline derivatives (Figure 1a). The dihydroquinoxaline products were all obtained with excellent yields and er values. It is worth noting that Lactka and co-workers have pioneered the asymmetric construction of the cyclic “C–N–C–C–N–C” fragment with ketene enolates and the cyclohexadiene-1,2-diimines through a cooperative catalytic strategy with chiral cinchona alkaloid catalysts and achiral Lewis acid cocatalysts.^{3a} The key enolate intermediates in Lactka’s and our studies are different. Our approach involves acylazolium enolate generated from aldehyde substrates under NHC catalysis, which possesses different reactivities from Lactka’s enolate intermediates generated from acyl chlorides (via ketenes) and cinchona alkaloids.^{3a} The Lewis acid cocatalysts used in Lactka’s approach are not required in our approach.

Different NHC precatalysts were first examined for this aza-[2 + 4] cycloaddition reaction between α -chloroaldehyde **1a** and cyclohexadiene-1,2-diimine **2a** (Table 1, entries 1–6). The *N*-mesityl substituted triazolium NHC precatalyst **A**¹³ derived from an amino-indanol skeleton could give the product **3a** in better yield and er value than those bearing an *N*-Ph¹⁴ or *N*-pentafluorobenzene¹⁵ group (entry 1 vs entries 2–3). The product yield could be further increased by switching the NHC precatalyst **A** into the corresponding chloride salt **D**¹⁶ (entry 4). Other NHC precatalysts we tested did not provide any better results in this transformation (e.g., entries 5–6). Organic bases generally gave the enantioenriched dihydroqui-

^aGeneral conditions (unless otherwise specified): **1a** (0.15 mmol), **2a** (0.10 mmol), NHC (0.02 mmol), base (0.15 mmol), 4 Å MS (50 mg), solvent (1.0 mL), rt, 24 h. ^bIsolated yield of **3a**. ^cEr was determined via HPLC on chiral stationary phase.

noxaquine products in lower yields, while the inorganic bases we tested could provide us with the products in better yields without erosion of the enantioselectivities (e.g., entries 7–9). To our delight, NaOAc could give the product **3a** in up to 88% isolated yield with an excellent 98:2 er value (entry 9). Additional screening of the reaction solvents could not further increase either the product yield or er value (entries 10–12).

With the optimized reaction conditions in hand, we next examined the reaction scope using α -chloroaldehydes with different substituents or substitution types (Scheme 1). Both

Scheme 1. Scope of α -Chloroaldehydes **1**^a

^aReaction conditions as stated in Table 1, entry 9. Yields are isolated yields after purification via SiO₂ column chromatography. Er values were determined via HPLC on chiral stationary phase. ^bThe reaction was carried out at 1.0 mmol scale. ^c α -Chloroacetaldehyde (40% aq.) was used as the reaction starting material.

electron-donating and electron-withdrawing groups could be installed on the β -phenyl ring of the α -chloroaldehyde **1**, with the corresponding dihydroquinoxaline products **3** afforded in good to excellent yields with excellent enantioselectivities (**3b** to **3k**). The β -phenyl ring of the α -chloroaldehyde **1a** could also be switched to aliphatic groups, with both of the product yields and er values remaining high (**3l** to **3m**). The benzyl group on the α -chloroaldehyde **1a** could be replaced with a phenyl group (**3n**), and α -chloroacetaldehyde could react fine as well (**3o**), albeit with low yields under the standard conditions without additional optimizations. As a technical note, the formation of chiral products **3n** and **3o** was not reported in Lectka's study.³

Various substituted cyclohexadiene-1,2-diimine **2** also worked well in this asymmetric cycloaddition reaction (Scheme 2). Cyclohexadiene-1,2-diimines bearing electron-

^aReaction conditions as stated in Table 1, entry 9. Yields are isolated yields after purification via SiO₂ column chromatography. Er values were determined via HPLC on chiral stationary phase. ^bRegioselective ratios of the products **3u**/**3u'** were determined by ¹H NMR of the isolated mixture of both products and confirmed by X-ray analysis.

withdrawing groups gave the corresponding products in lower yields, which were probably due to the decomposition of the unstable starting materials under the current reaction conditions (e.g., **3p**). However, electron-rich cyclohexadiene-1,2-diimines **2** could give the desired products in good to excellent yields with excellent enantioselectivities, regardless of the substitution patterns existing on the α -chloroaldehyde **1** used in these transformations (**3q** to **3t**, **3u**/**3u'**). It is worth noting that the electron-donating group existing on the cyclohexadiene-1,2-diimine **2** could decrease the electrophilicity of the imine group on its para-position due to the conjugate effect, which might result in the good regioselectivities observed in the formation of the products **3u**/**3u'**. The absolute configurations of the products **3** were assigned based on the X-ray analysis on the single crystal of the product **3b**.

In addition to α -chloroaldehydes, saturated aldehydes (such as 3-phenylpropionic aldehyde) could also be used as substrates to generate the azolium enolate intermediates under oxidative NHC catalysis (Scheme 3). For example, with **DQ** used as an oxidant, dihydroquinoxaline product **3a** could be formed from 3-phenylpropionic aldehyde (**4a**) with a 47% yield and excellent enantioselectivity by using the same NHC catalyst (**D**). Phenyl acetaldehyde could also be used in this oxidative [2 + 4] cycloaddition reaction to form product

Scheme 3. Saturated Aldehyde as Enolate Precursor under Oxidative NHC Catalysis

3n with excellent enantioselectivity, albeit with a low yield under current conditions.

To demonstrate the operational simplicity of our NHC-catalyzed enolate reaction for the synthesis of chiral dihydroquinoxaline derivatives, we next combined the substrate preparation step and the NHC catalytic reaction step in a one-pot operation. The cyclohexadiene-1,2-diimine substrates (**2**) used in our reactions (Schemes 1 and 2) were prepared via oxidation of the corresponding diamide substrates (e.g., **5a** and **5b**, Scheme 4). This substrate preparation step can be combined with the NHC catalytic step in a one-pot operation to furnish the cycloaddition products (**3a** and **3q**, Scheme 4).

Scheme 4. One-Pot Operation by Combining Substrate Preparation with NHC-Catalyzed Cycloaddition

The Bz group on the lactam moiety of the chiral dihydroquinoxaline **3a** could be selectively removed under basic conditions to give product **6** in good yield with little erosion of the product er value.¹⁷ The lactam moiety of **3a** could also be stereoselectively reduced by BH₃·THF to afford the secondary amine product **7** in good yield with a slight increase of the optical purity.¹⁸ Both of the Bz protecting groups could be removed with the assistance of Red-Al, and the corresponding amide **8** could be formed in 78% yield with retention of the enantioselectivity.¹⁹ Lactam **8** could be further reduced by BH₃·THF and give the diamine product **9** in good yield with an excellent er value (Scheme 5).

Scheme 5. Synthetic Transformations of **3a**

In summary, we have developed an NHC-catalyzed amination and cycloaddition reactions of α -chloroaldehydes. In our reaction, cyclohexadiene-1,2-diimine compounds were used as amination reagents and four-atom synthons, with two C–N bonds formed. The reactions afford substituted dihydroquinoxaline derivatives with excellent enantioselectivities. The chiral dihydroquinoxaline products afforded in this reaction could be efficiently transformed to various functional molecules via simple protocols. Further synthetic transformation and bioactivity evaluation of the dihydroquinoxalines are in progress in our laboratory.
